ntroduction

Appropriate education of onco-/haematological patients is a prerequisite to improve patient empowerment, hereby facilitating shared decision making. Clinical pharmacists are proven to be an asset to the multidisciplinary team as drug experts, focusing on pharmacotherapeutic consequences for the patient and his/her drug therapy after an antitumor treatment has been initiated.

To quantify patients' information need and satisfaction on antitumor drug therapy and how this can be improved by clinical pharmacist's counselling. Additionally, the pharmacist's impact on therapy quality and costs was assessed.

Methods

- Setting: prospective, randomised study in the ambulatory (26 beds) and in-hospital onco-/haematology unit (34 beds) in a tertiary care university hospital.
- Inclusion criteria: adult patients receiving a new course of intravenous or oral antitumor treatment, after informed consent.
- Data collection process & analysis:

RANDOMISATION (1:1) Oral/IV Ambulatory/In-hospital care After consult with physician, dietician and social worker 1st patient contact * = baseline Desire for Information (EID) Cancer Treatment Education (PS-CaTE)

INTERVENTION: Clinical pharmacist

medication reconciliation/review + patient counselling with each contact

CONTROL:

Standard of care

anticancer drug prescribed by physician, dispensed by hospital pharmacy, administration-related information provided by nurse

*Evaluation based on questionnaires, scoring with 5-point Likert scale: EID = Extent of Information Desired

PS-CaTE = Patient Satisfaction on Cancer Treatment Education

Subcategories: Cancer treatment, Side effects, Information sources, Overall satisfaction CTSQ = Cancer Treatment Satisfaction Questionnaire

On administration of 2nd cycle

2nd patient contact

After 2-3 months of treatment

3rd patient contact

- EID
- PS-CaTE
- Treatment Satisfaction (CTSQ)
- EID PS-CaTE
- CTSQ

Registration of pharmaceutical interventions throughout treatment

- EID
- PS-CaTE
- PS-CaTE

EID

- CTSQ
- CTSQ

Input of scores on questionnaires in MS Access database, followed by statistical

analysis using SPSS 23.0

Outcomes

- Eighty-three patients included over a period of six months (10/2015 3/2016)
- Control (N=43); intervention (N=40)

Table 1 Patient characteristics

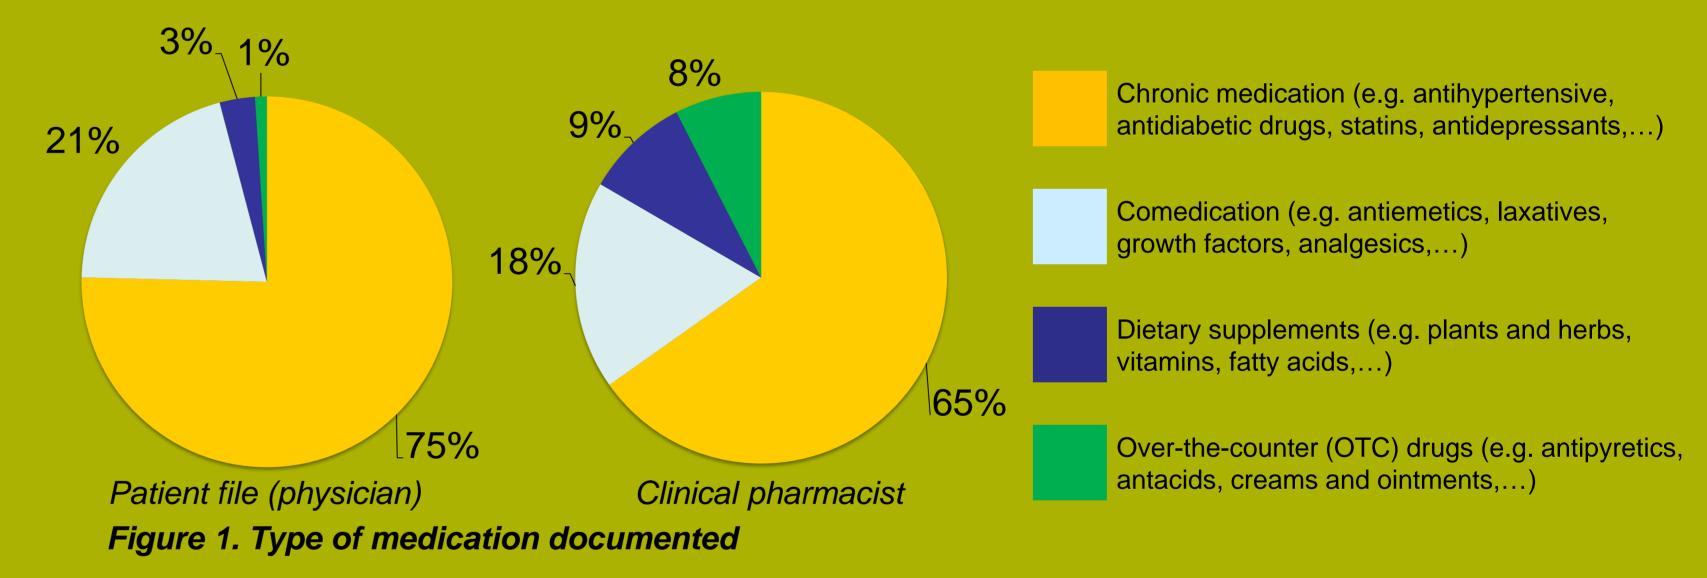

Patient characteristics	Control	Intervention
Median age (IQR)	63,0 (56,0 – 74,0)	63,0 (53,5 – 70,5)
Gender		
Man / Woman	15 / 28	15 / 25
Department		
Ambulatory care / In-hospital unit	34 / 9	31 / 9
Number of course		
1st therapy / Salvage therapy	21 / 22	27 / 13
Administration route		
Oral / IV / Both	3 / 39 / 1	1/37/2
Karnofsky score		
90-100 / 70-80 / 50-60 / <50	36 / 4 / 3 / 0	28/9/0/3

- Questionnaires EID / PS-CaTE / CTSQ:
 - scores between patient contact moments (1 2 3): P > 0,05
 - scores between patient groups (control vs. intervention): P>0,05
- Intervention patient data showed patients' satisfaction on SE education was positively correlated with the contact moment (r_s = 0,198; P=0,022). A similar trend was seen in a multiple linear regression analysis (B=0,207; P=0,101; R²=0,128).
- Patients receiving an antitumor treatment either for the first time or in ambulatory care, were significantly more satisfied on side-effect education than patients on salvage therapy or in-hospital setting (Table 2).

Table 2. Multiple linear regression analysis for all patient data, with PS-CaTE SE as dependent variable

Variable				
Model (R ² =0,127; <i>P</i> <0.001)	В	P		
1 st therapy	0,261	,000		
Ambulatory care	0,156	,018		

- Drug reconciliation done by the clinical pharmacist showed (Figure 1):
 - higher number of drugs documented vs. patient file (8,0 vs. 4,9);
 - more chronic medication recorded (5,2 vs. 3,7);
 - less comedication documented (1,0 vs. 1,4);
 - more thorough registration of dietary supplements (0,7 vs. 0,2) and OTCdrugs (0,6 vs. 0,05).

- Patient follow-up during first 2-3 months of treatment (Table 3):
 - 48% of patients had a drug therapy requiring pharmaceutical intervention;
 - pharmacist intervened mostly on drug related problems (45%). and patient counselling (20%);
 - shift in type of intervention (drug related -> patient education);
 - physician acceptance rate on drug related interventions = 72%.
- Assessment of active antitumor treatments and medication stock optimalisation lead to a savings of €36 890.

Table 3. Interventions on drug therapy

Interventions	1 st contact (N=40)	2 nd contact (N=36)	3 rd contact (N=29)
Total	40	36	17
Number of patients	19 (48%)	13 (36%)	9 (31%)
Number of interventions per patient (mean ± SD)	2,1 ± 1,4	2,8 ± 3,1	1,9 ± 0,9
Drug related problems	32	19	4
Patient education/advice	5	12	7

Conclusion

- Pharmaceutical counselling should be repeated and primarily focused on side-effect management to have a meaningful impact on patient satisfaction.
- · Hospitalised patients and patients receiving salvage therapy appear to have higher educational needs on side-effects, making them possibly overlooked target groups.
- Physicians tend to underregistrate chronic medication, dietary supplements and OTC-drugs, stressing the clinical pharmacist's role to improve drug reconciliation.
- Pharmaceutical intervention should focus on medication review at treatment startup, followed by adequate patient education.
- Involving the pharmacist in the prescribing process enhances stock management, leading to significant cost savings.
- Currently used questionnaires may not be sensitive or specific enough to detect changes in patient satisfaction upon pharmacist intervention.
